Individual Contribution and Tool Use

NewsLens | Track B Demonstration | Yi Tan (2312260)

Responsibilities and delivered work

Yi Tan is the sole team member and is responsible for the project question, data audit, fixed experimental split, model comparisons, calibration and explanation design, local interface, tests, result interpretation, written materials, and presentation. This responsibility statement does not claim that every line of source or prose was authored without assistance.

Verifiable work is stored under src/, tests/, templates/, scripts/, artifacts/, and the stage-specific PDF folders. A training task counts as completed only when its metrics and per-example predictions pass the submission verification script. Future plans are not listed as accomplished results.

Prior resources and project-specific contribution

Prior resources include course-provided CSV files, Stanford GloVe vectors, Google BERT weights, scikit-learn logistic regression, Gensim Word2Vec, PyTorch, Transformers, Flask, and the unmodified official ACL style. Their underlying algorithms and code remain the work of their respective authors.

Project-specific work comprises the shared data protocol and checksum, disjoint validation calibration and threshold selection, exact relative term contributions, feature-deletion diagnostic, local interactive demo, input handling, tests, per-example predictions, and analysis of validity limits. Public course and news-classification repositories were examined as examples of reproducible packaging and reporting; no third-party assignment code or results were imported into this implementation.

AI assistance and student review

Codex assisted with reading the requirements, drafting and revising code and English prose, executing experiments, debugging the environment, recording results, and producing the PDF materials. Numerical findings come from actual program output; uncompleted experiments are identified explicitly until run. This document is a disclosure, not a signature or a claim that a future oral presentation has already occurred.

Before submission, the student should review the source and reports, run the demo, and be prepared to explain split leakage controls, logistic regression, averaged embeddings, BERT fine-tuning, temperature scaling, threshold selection, and the contribution equation.
